In recent years, the use of HPLC-MS for the analysis of flavonoids and related compounds in foods and biological samples has significantly enhanced our understanding of (poly)phenol bioavailability. These advancements have also led to improvements in the available food composition and metabolomic databases, and consequently in the development of biomarkers of (poly)phenol intake to use in epidemiological studies.

Lipid-based nanoparticles composed of physiologically acceptable lipid vehicles have emerged as another feasible drug delivery system because they can encapsulate large amounts of hydrophobic flavonoid compounds, thereby enhancing drug solubility, protecting the drug from degradation in the gastrointestinal tract, and increasing the total systemic bioavailability via the enhanced permeability and lymphatic absorption (Ahn and Park, 2016, Teixeira et al., 2017). According to the physical ...

Bioavailability of flavonoids Biological activity of flavonoids is often assessed by using in vitro models; in almost all such studies, cells are treated with aglycones and data are reported at concentrations that elicited a response. However, plasma and tissues are not exposed in vivo to flavonoids in these forms.

Therefore, a clear understanding of uptake, metabolism and bioavailability of these compounds is crucial to elucidating their health benefits/adverse effects. Most common isoflavones exist as O-glucosides (e.g., daidzein and genistein), and, compared to their aglycones form, the glycoside forms are poorly absorbed from the small intestine into the blood due in large part to their high hydrophilicity [16 , 17].

The few bioavailability studies in humans show that the quantities of polyphenols found intact in urine vary from one phenolic compound to another . They are particularly low for quercetin and rutin, a glycoside of quercetin (0.3–1.4%), but reach higher values for catechins in green tea, isoflavones in soy, flavanones in citrus fruits or anthocyanidins in red wine (3–26%).
