even though the input is a random variable, quicksort will always execute the same behavior. Consequently, the algorithm is deterministic. In the second case, however, multiple executions could produce different behavior on the same input, so the algorithm is randomized, and performance is a random variable.

An algorithm that uses random numbers to decide what to do next anywhere in its logic is called a Randomized Algorithm. For example, in Randomized Quick Sort, we use a random number to pick the next pivot (or we randomly shuffle the array). And in Karger's algorithm, we randomly pick an edge. How to analyse Randomized Algorithms? Some randomized algorithms have deterministic time complexity. For example, this implementation of Karger's algorithm has time complexity is  $O(E)$ .

During this period, randomized algorithms went from being a tool in computational number theory to finding widespread application in many types of algorithms. Two benefits of randomization have spearheaded this growth: simplicity and speed. For many applications, a randomized algorithm is the simplest algorithm available, or the fastest, or both.
